Web Application Development Tutorial 2 – JavaScript Forms & Validation

Due Date: Monday October 5, 2026

Group 10

Quick Check Test

1. What does .value do?

.value is a property that allows for the retrieval of input data from HTML elements or to change the data the user enters in a form.

2. What does event.preventDefault() do?

This is a method of the event interface that the event is being explicitly handled, therefore, its default action is cancelled. For example, submitting a form, link navigation and page scrolling should not be taken.

3. What is the purpose of addEventListener()?

This is a method that is used to attach an event handler to an element in the DOM (Document Object Model). It listens for specific events such as click, key down or submit on that element and executes a function when the event occurs.

4. What does === mean?

This is the strict equality operator used to see if two values are exactly the same.

5. Why validate form data?

- It ensures that the user input has the correct data in the right format.
- Improves user experience
- Gives immediate feedback preventing mistakes before submission.

6. Difference between client-side and server-side validation?

Client side validation occurs in the users browser before data is sent to the server, allowing for correction of errors, while Server-side validation occurs after data has been submitted to the server, ensuring no malicious or incorrect data bypasses client side validation.
